01

AI Concepts

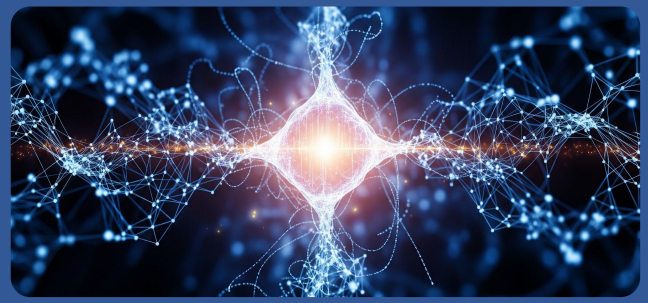

Working With AI Agents

Level 1: Prompting

Instant prediction based on pre-trained weights. Best for simple drafting and general Q&A.

- Cost Multiplier 1x
- Complex Task Success Rate 10-20%
- Human Intervention Rate 100%

Level 2: Reasoning

Internal monologue for planning and self-correction. High accuracy for complex logic and math.

- Cost Multiplier 5x - 10x
- Complex Task Success Rate 40-50%
- Human Intervention Rate 40-50%

Level 3: Agentic Harness

Software "harness" provides tool access. AI performs, tests, and iterates tasks autonomously.

- Cost Multiplier 20x - 100x
- Complex Task Success Rate 70%+
- Human Intervention Rate 10%

Indicative figures from Makeitfuture project experience — not a benchmark.

SKILLS

Capture Expert Knowledge

What are AI Skills?

Two types of AI skills

AI SKILLS / TWO TYPES

CAPABILITY UPLIFT

Teaches the agent a task it cannot do reliably yet.

EXAMPLES

PDF forms / web design
slide decks

LIFESPAN

May become obsolete as models improve.

TEST

Can the newest model do it without the skill?

IF YES → RETIRE THE SKILL

AI SKILLS / TWO TYPES

ENCODED PREFERENCE

Teaches the agent how your team wants the work done.

EXAMPLES

NDA review / code review
client onboarding

LIFESPAN

Stays useful while your process matters.

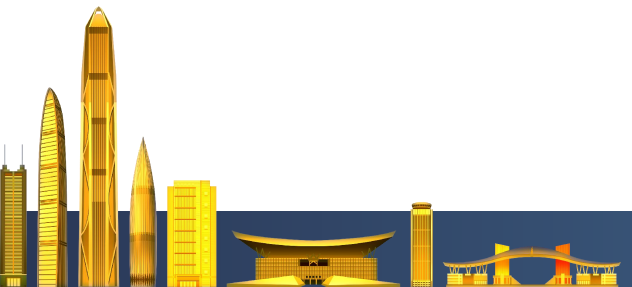

TEST

Does it follow your exact steps, in the right order?

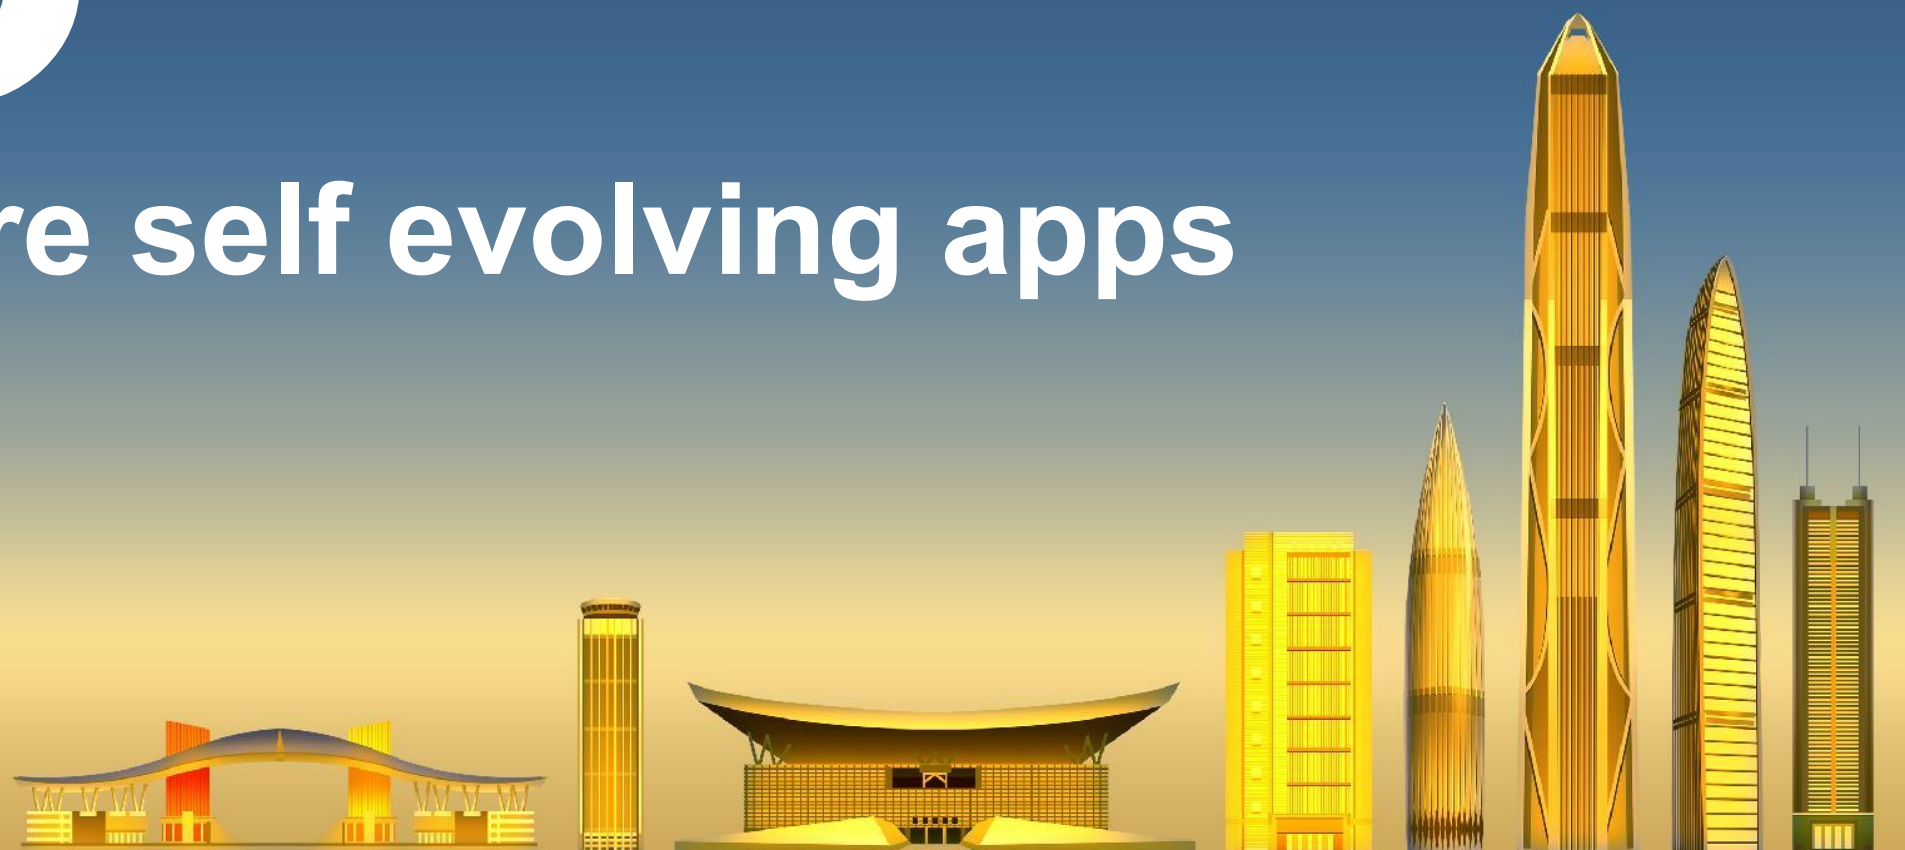

IF NO → REFINE THE SKILL

Different purpose. Different test.

03

What are self evolving apps

What is a self-evolving app?

An app that gets better every time you use it — without code changes and without retraining a model.

01 Behaviour lives in files

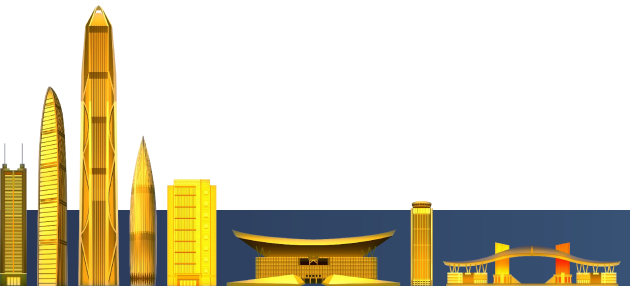

Skills, Agent.md, permissions and MCP connections define what the app does — not hard-coded logic.

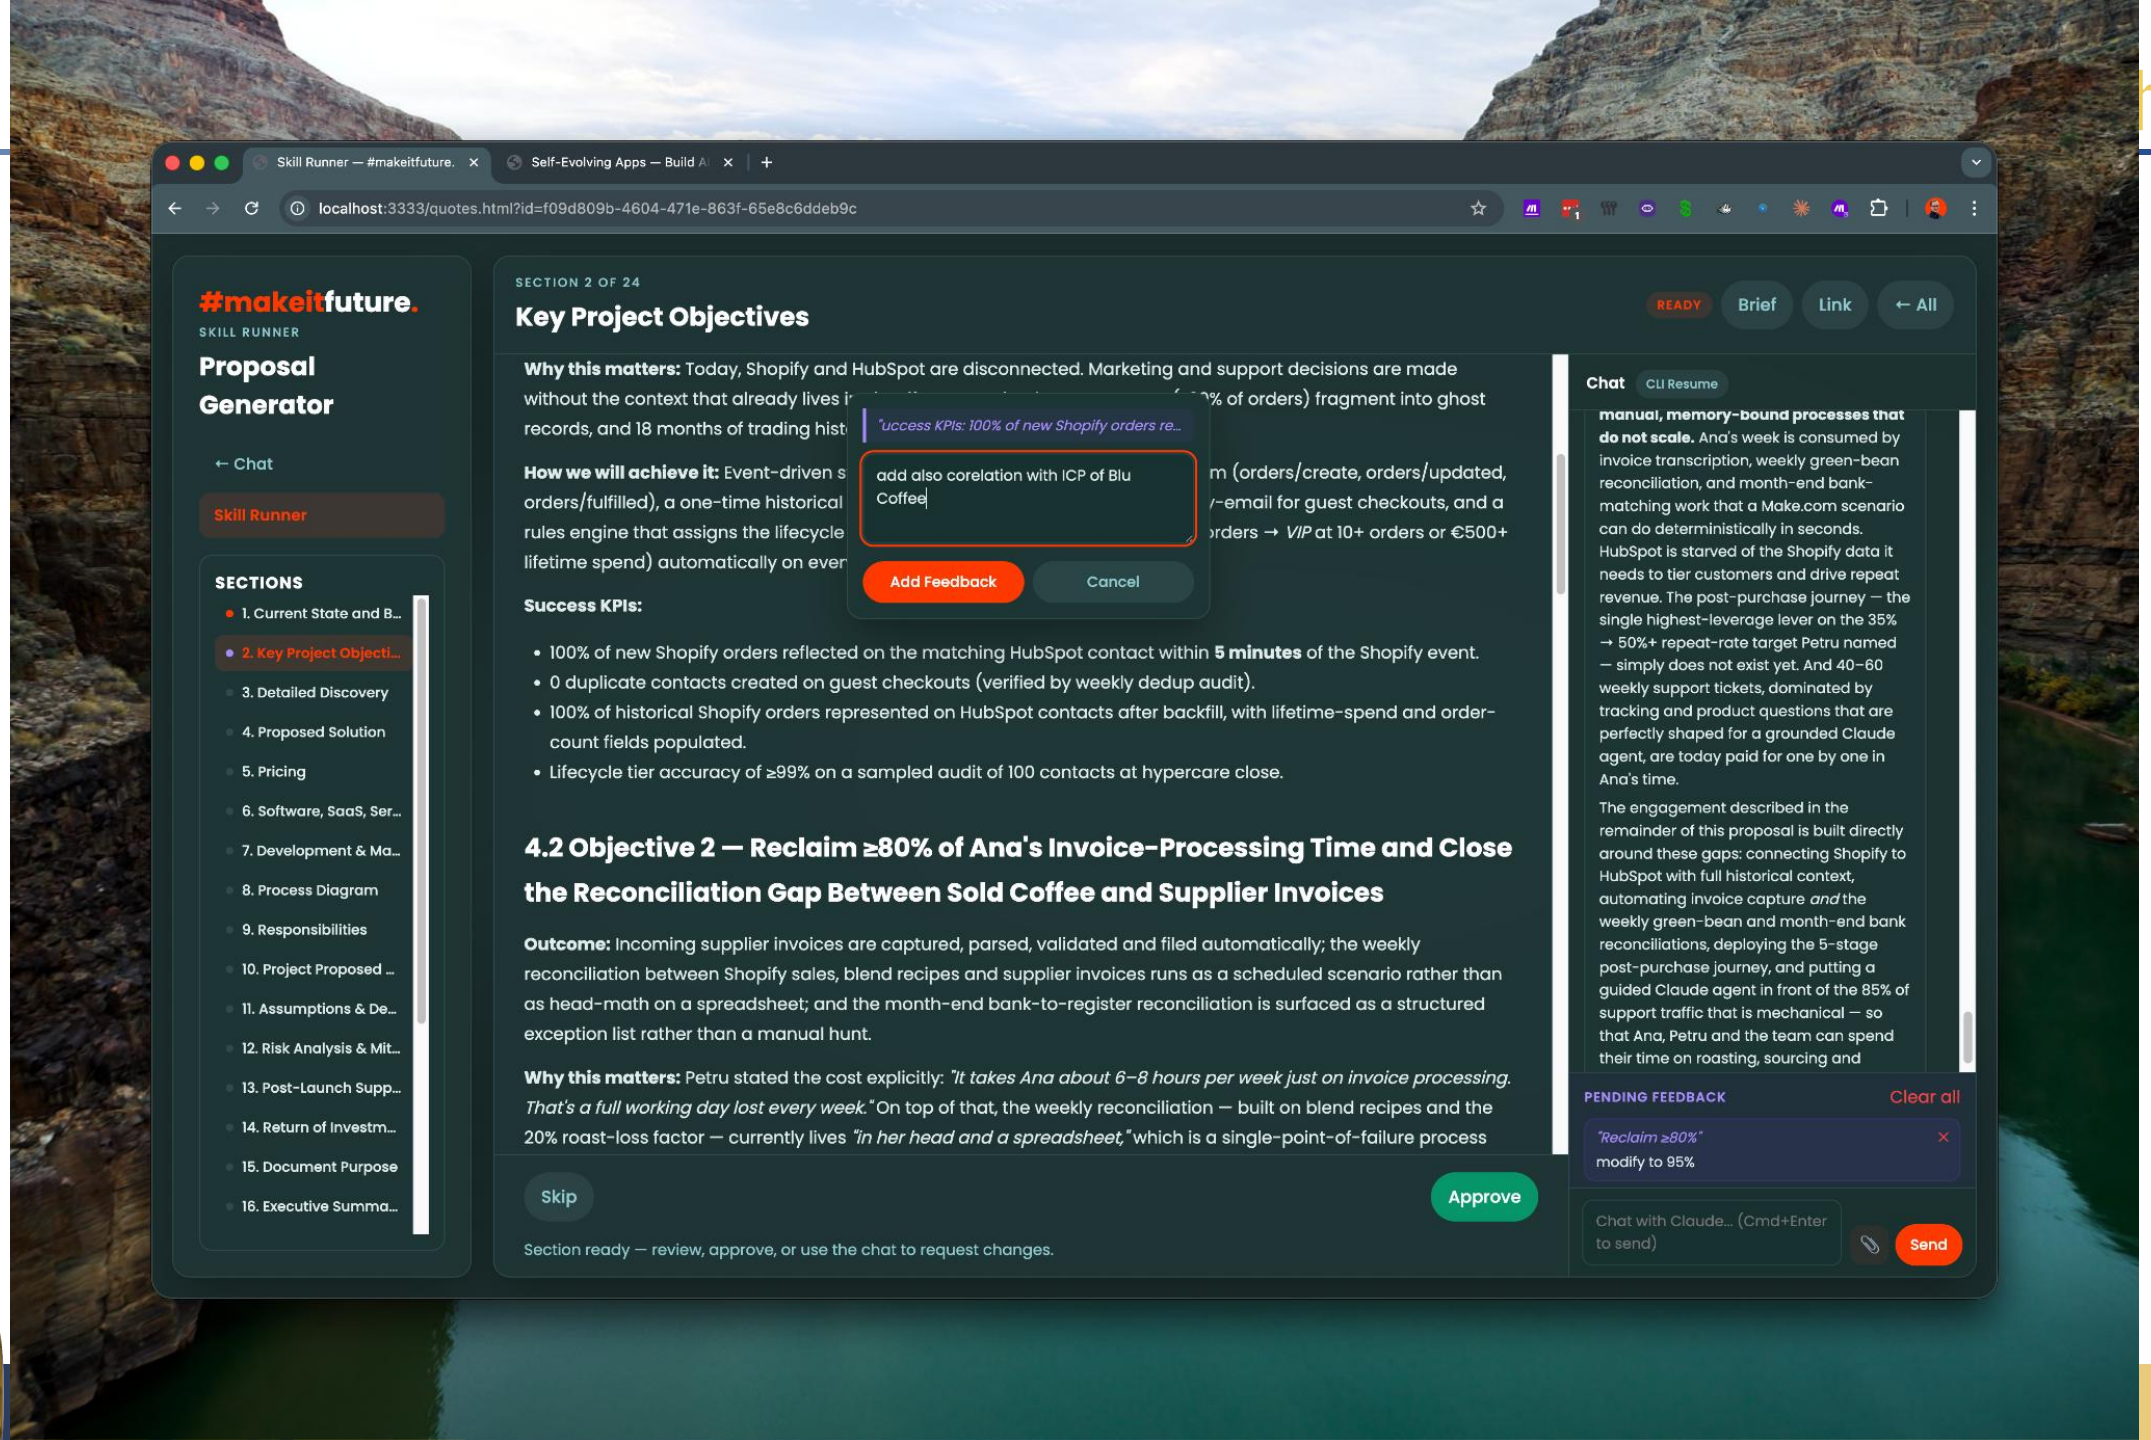

02 An agent runs underneath

Claude Code, Codex, Copilot or Gemini CLI does the work inside the app's own folder.

03 Feedback rewrites the skills

User corrections become skill updates, so the next run is better. A human approves the change.

How we will achieve it: Event-driven s m (orders/create, orders/updated, orders/fulfilled), a one-time historical /-email for guest checkouts, and a rules engine that assigns the lifecycle orders → VIP at 10+ orders or €500+ lifetime spend) automatically on ever
Success KPIs:
100% of new Shopify orders reflected on the matching HubSpot contact within 5 minutes of the Shopify event.
0 duplicate contacts created on guest checkouts (verified by weekly dedup audit).
100% of historical Shopify orders represented on HubSpot contacts after backfill, with lifetime-spend and order-count fields populated.
Lifecycle tier accuracy of ≥99% on a sampled audit of 100 contacts at hypercare close.
4.2 Objective 2 — Reclaim ≥80% of Ana's Invoice-Processing Time and Close the Reconciliation Gap Between Sold Coffee and Supplier Invoices
Outcome: Incoming supplier invoices are captured, parsed, validated and filed automatically; the weekly reconciliation between Shopify sales, blend recipes and supplier invoices runs as a scheduled scenario rather than as head-math on a spreadsheet; and the month-end bank-to-register reconciliation is surfaced as a structured exception list rather than a manual hunt.
Why this matters: Petru stated the cost explicitly: "It takes Ana about 6–8 hours per week just on invoice processing. That's a full working day lost every week." On top of that, the weekly reconciliation — built on blend recipes and the 20% roast-loss factor — currently lives "in her head and a spreadsheet," which is a single-point-of-failure process

manual, memory-bound processes that do not scale. Ana's week is consumed by invoice transcription, weekly green-bean reconciliation, and month-end bank-matching work that a Make.com scenario can do deterministically in seconds. HubSpot is starved of the Shopify data it needs to tier customers and drive repeat revenue. The post-purchase journey — the single highest-leverage lever on the 35% → 50%+ repeat-rate target Petru named — simply does not exist yet. And 40–60 weekly support tickets, dominated by tracking and product questions that are perfectly shaped for a grounded Claude agent, are today paid for one by one in Ana's time.
The engagement described in the remainder of this proposal is built directly around these gaps: connecting Shopify to HubSpot with full historical context, automating invoice capture and the weekly green-bean and month-end bank reconciliations, deploying the 5-stage post-purchase journey, and putting a guided Claude agent in front of the 85% of support traffic that is mechanical — so that Ana, Petru and the team can spend their time on roasting, sourcing and

Self-Evolving Apps Architecture

Self Evolving Apps Architecture - How it works

The evolution loop

1 Use

The user runs the app: e.g. generates a proposal.

2 Feedback

The user comments on or corrects a section, in plain language.

3 Evolve

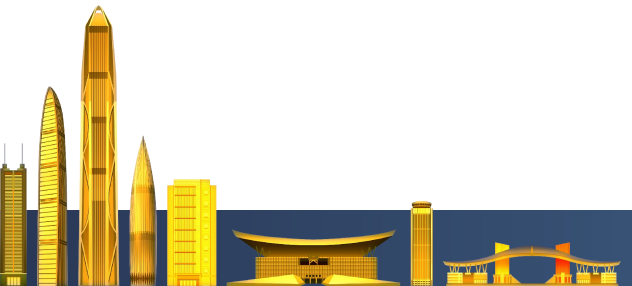

The agent updates the skill, Agent.md or MCP setup.

4 Approve

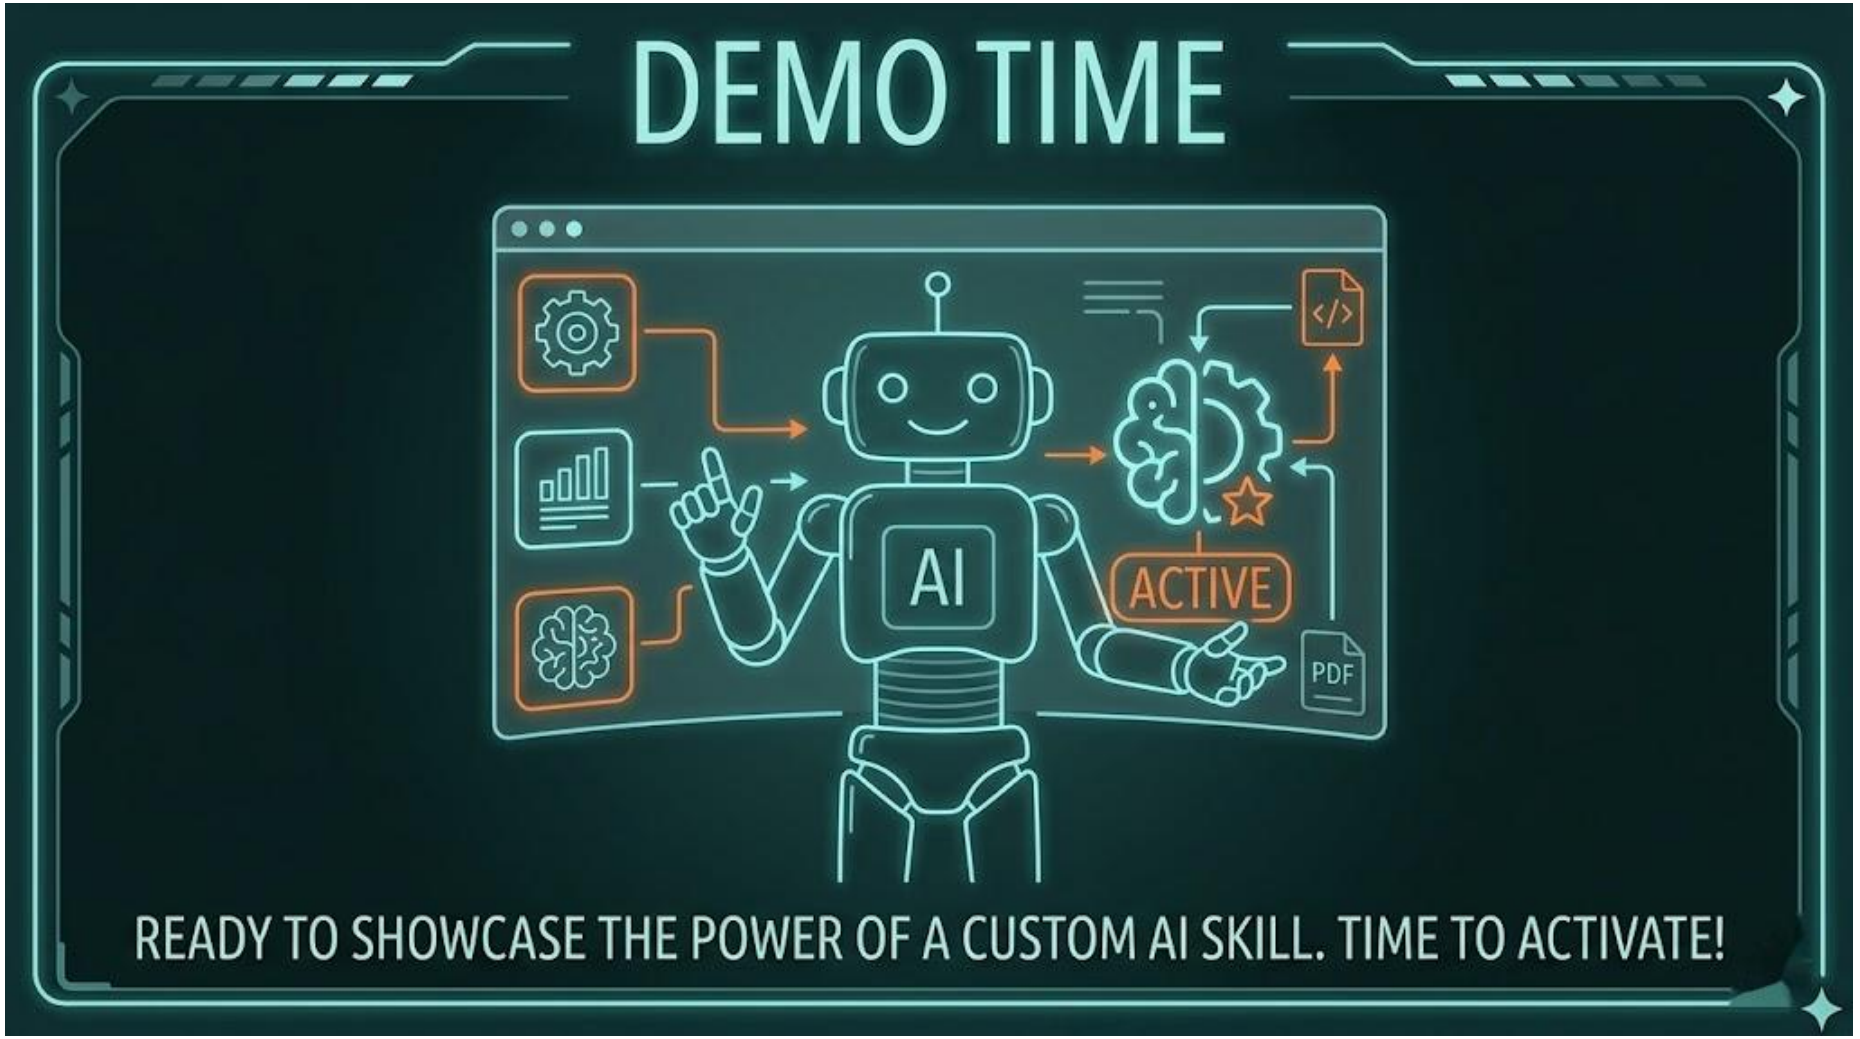

A human reviews the change. The next run starts smarter.

REPEAT

Repeat. Every run makes the next one better. No redeploy or retraining needed.

Demo: a self-evolving app, live

Guardrails: how the app evolves safely

Human in the loop

The agent proposes changes; a person approves or skips them.

Scoped permissions

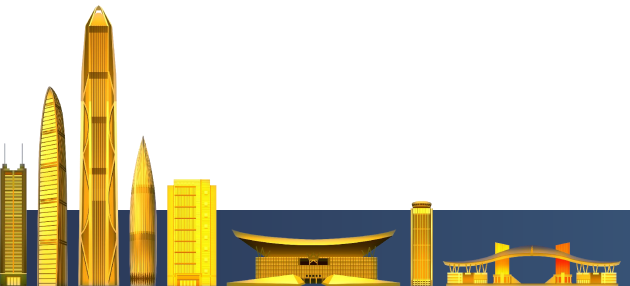

The agent only works inside the app's folder, with the tools and MCPs you allow.

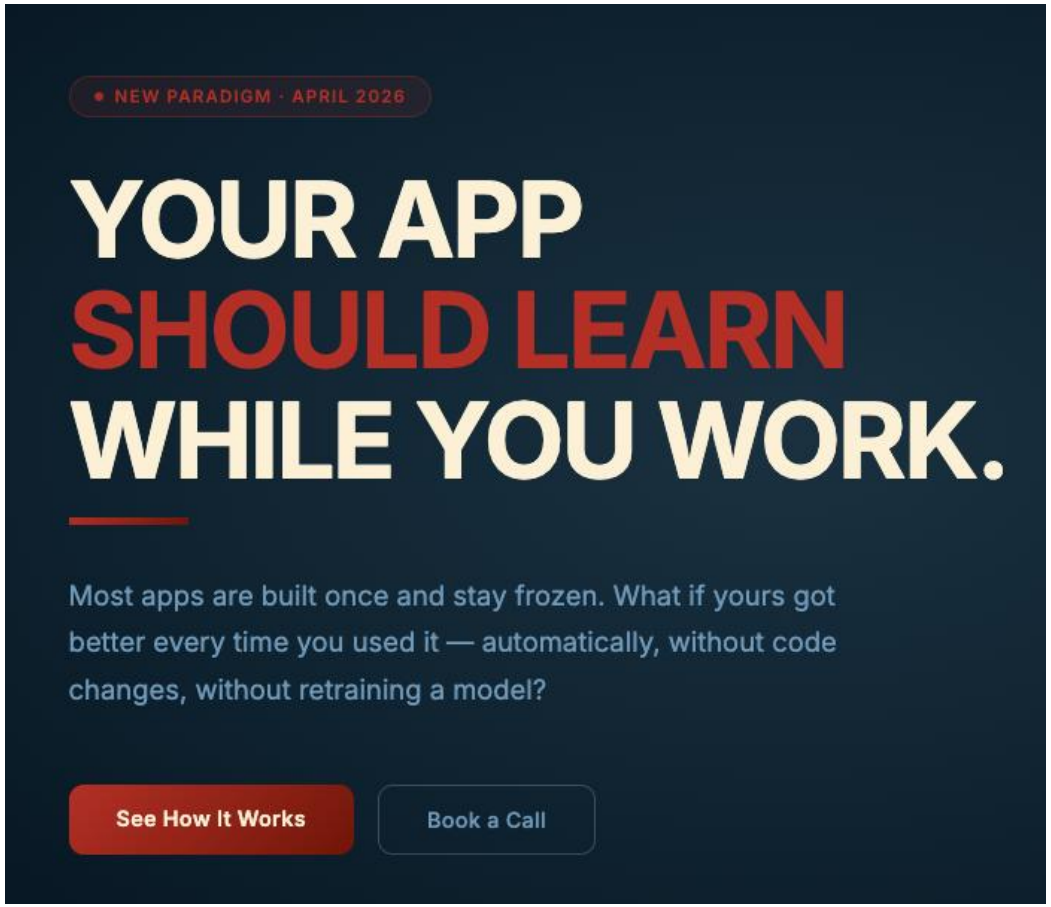

Skills are plain files

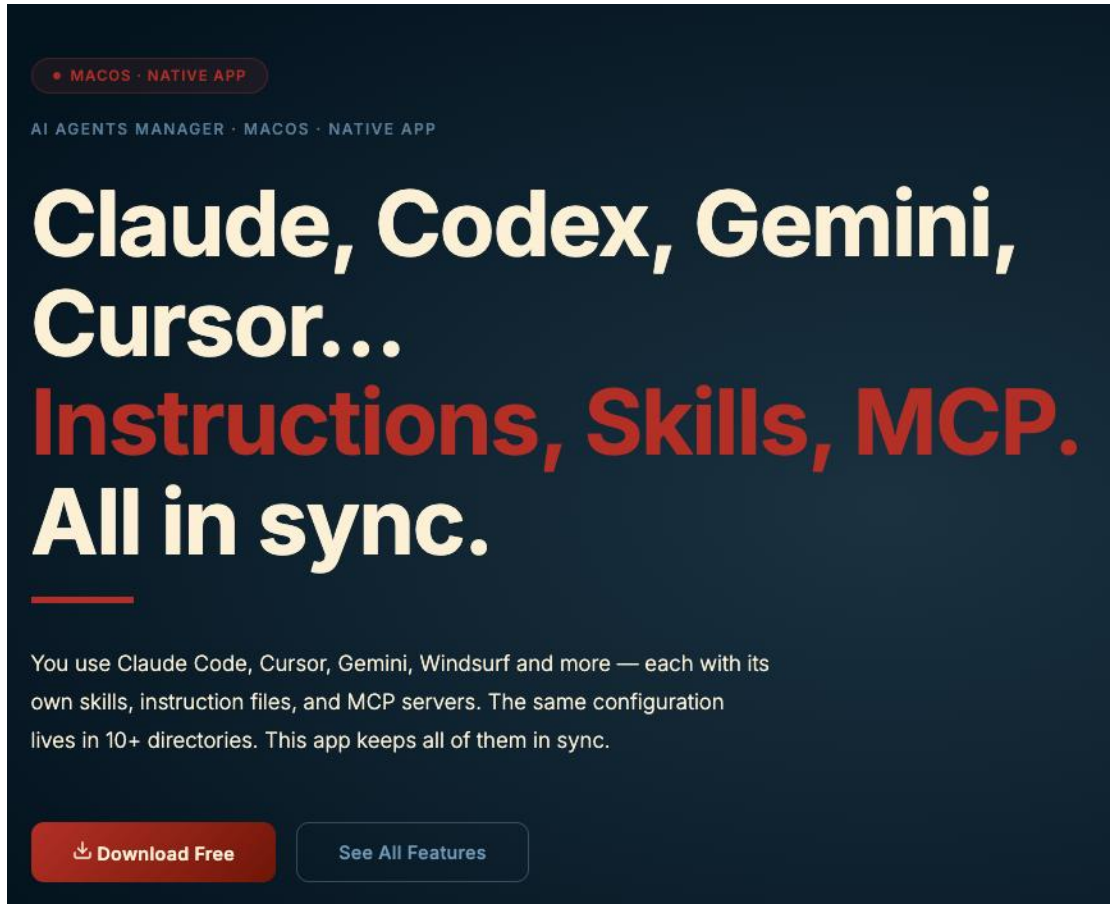

Keep them in git: every change can be reviewed, compared and rolled back.

Test the skills

Capability skills: does a newer model beat them? Preference skills: is the workflow still followed exactly?
